THE GARLAND GLOBE SATURDAY, MAY 8, 1909.

METHODS FOR CONTROL By E. D. Ball, Agricultural Experi-

ment Station, Logan, Utah. codling moth has not been the result has also tested dilute solutions of arof the work of any one man, or even senate of lead with good results. of one generation of men. Banding and scraping the bark were practiced by our forefathers. No satisfactory remedy, however, was known for the pest until after the discovery of the value of spraying with the arsenicals for leaf-eating caterpillars, that they would be far more successwhich was made in the early '70s. While using this remedy for other used at present. Several of the insects it was found that the codling Eastern states have since that time moth was reduced in numbers at the tried this method, and some of them same time. From this accidental have had very good success. Profesdiscovery has arisen, by slow steps. the method of control used in the Eastern states today, To control the leaf-eating insects it was necessary to use a fine mist spray. They methods. were also troubled with fungi and soon learned to mix bordeaux with it, and this triple combination spray it, and this triple combination spray the standard of the Northwest in its is largely used up to the present time. production of fruit. "Nothing short Spraying for everything at once of extermination," it its attitude to means spraying for nothing in particular, and as a result it was necess-that it is attaining very close to its ary to put on a large number of ideal in both directions. sprays to accomplish the purpose. and even then the results were poor, eighty to eighty-five per cent of sound annies being the exception ing can no doubt be done and fair rerather than the rule. Several men sults obtained even where one or two were conspicuous in helping develop of the points mentioned are neglect-these methods, and in adding to our it is well for those who wish to do knowledge of the life habits of the the very best work to modify this insect. Professor Cook of Michigan practice but little. and Professor Forbes of Illinois per-fected the use of the arsenicals. Dr. Howard, of the Government Bureau, added much to our knowledge of the where founded insect. Professor Card of Nebraska why it is done. insect. Professor Card of Nebraska why it is needed for giving a summary of found out where eggs were laid, is needed for giving a summary of while Professor Slingerland of Cornell gave us the most complete treasely ever is a small shy creature, rarely ever nell gave us the most complete treasen, flying only in the dusk of the seen, flying only in the dusk of the cornel gave and then with a rapid zig-

While this was going on in the East, Western orchards were growing and the codling moth, with the spirit of the age, migrated westward and through its rapid multiplication under our favorable climate soon threatened the destruction of our growing fruit industry. With the rapid increase in the number of worms to fight came a corresponding decrease in the success obtained, and a large number of the fruit growers became discouraged. To cap the climax the word went forth that the poisons were being adulterated to such an extent that they were very little value and as a result many abandoned the fight. A few of the more persistent, however, only redoubled their labors, and as the worms increased, increased the number of sprayings and thus held their own in the contest. Professor Simpson was sent out by the Government to introduce the Eastern method of spraying. Through the fact that he used power sprayers he succeeded in obtaining even better results than they had obtained in the East. He weeks, when they appear as mother weeks. evidently did not realize the impor-tance of the extra power applied in to lay eggs for the second brood. The getting these results, however, as he was very careful to recommend the use of a fine mist and gave directions to cense spraying as soon as the trees began to drip.

just at the time when things were a long period, many people have de-at their worst. The worms were insupposed to follow another in quick been carefully investigated throughsuccession: the polson was said to be adulterated, and many people who had formerly been successful were now losing their crops and knew not why. The writer had worked on that we can figure with absolute certific to the succession of the larger part of the apple growing region, two broods and two only have been found. The great value of this knowledge lies in the fact why. why. The writer had worked on this insect with Professor Gillette in Colorado for five years, and as a result of these studies the Professor published the statement that the insect produced only two broods annually in that state. The first season's work in Utah convinced the writer that the insect had the same number of broods in this section as it had in Colorado, and he also succeeded in proving by experiment the great value of the driving spray. Armed with these results, this method of spraying was publicly advocated and presented to the Northwestern Fruit Growers' Association in Portland in January, 1904. This was its first presentation to any horticultural body, and its reception was ticultural body, and its reception was of six years of experimentation, that not flattering. Flattening, in fact, if a proper amount of poison is placnot flattering. Flattening, in fact, not flattering. In fact, not flattering the apple, that cription of just what happened at ninety-six or nipety-seven per cent that meeting. The same idea was, of the worms entering there will be killed, and that at the same time flattering the control of the apple, that the control of the apple of the app that meeting. The same idea was, however, presented the next year before the same association, at Boise, Idaho, but backed up with all the figures at the writer's command, as well as by the results obtained by Utah growers the previous year. Others by this time had tried the method and it was accorded a somewhat different reception. Bulletins were published on these experiments and further details given before the fruit growers' meeting at La Grande, Oregon, in 1906. Mr. Eldred Jenne published the results of an investigation on this insect's life history in the State of Washington, in 1905, and Professor Melander and Mr. Jenin the State of Washington in 1905, and Professor Melander and Mr. Jen-ne published the results of their first tests of this method of spraying

in 1906. The writer first suggested the possibility of controling this insect with a single spraying at the Boise meeting in 1906, but did not recommend it for the average grow-OF THE CODLING MOTH. er. Since that time, however, practical results in a number of orchards in Utah have warranted its recommendation, and Professor Melander's The development of the present ef- experiments in Washington have acient methods for the control of the confirmed this. Professor Melander

> The writer presented this method of spraying to the entomologists of the Eastern United States at their meeting in New York in 1906, with the suggestion that if they would apply the codling moth spray by itself and use the driving method, ful than with the combination spray sor Gossard of Ohio succeeded in obtaining ninety-seven per cent sound in one test with one early spraying. Such in brief is the history of the development of our present spraying

> > The Method in Detail.

"Nothing short of perfection" is wards the codling moth, and the results of the last few years have shown od of spraying here advocated is the one that has enabled Western orchardists to attain to their present supremacy, and while some of the details are matters of choice, and good spray-

The Codling Moth.

Better work will always be done where founded on a knowledge of zag motion hard to follow. In color it resembles the bark of the twigs with white stripes imitating the "bloom" that is always found on growing shoots. The eggs of first brood, tiny white specks, laid on the upper surface of the leaves, close to an apple, rarely ever on the apple itself. The majority of the second brood eggs are laid on the surface of the apples, but not in the calyx end, as formerly supposed. The little worms hatch and break through the top of the egg shell and immediately seek a hiding place, which the greater number of them find in the calyx end of the apples, and many of the remaining ones where two apples touch. The little worm bores down into the flesh of the apple, those of the first brood go-ing directly to the seeds in most cases. When full grown they bore out on the side of the apple, even where they went in at the calyx end, second brood of worms come down in the same way, but are more care-ful to find a good hiding place, spinning a tough cocoon in which they remain all winter. On account of the fact that the broods overlap and The writer came to Utah in 1962, that the second brood continues thru creasing in numbers, one brood was broods. But everywhere that it has
